(57) **ABSTRACT**

A method and apparatus for imprinting high quality images on non-planar surfaces, including the surfaces of various types of three-dimensional articles, such as baseball bats, formed from a number of different types of materials. In the preferred method of the invention, the non-planar surfaces of the three-dimensional articles are printed using a uniquely modified ink jet image transfer technique. The apparatus of the invention includes a modified ink jet printer coupled with a novel article positioning apparatus which functions to controllably rotate the article to be imprinted and to maintain the longitudinal axis of the article within a plane substantially parallel to and spaced apart from the plane within which the ink jet nozzles of the ink jet printer travel.

METHODS AND APPARATUS FOR IMAGE TRANSFER TO NON-PLANAR SURFACES

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to methods and apparatus for imprinting images on the surfaces of three-dimensional objects. More particularly, the invention concerns a novel, improved method and apparatus for non-contact, high-quality, distortion-free printing of images on non-planar surfaces of three-dimensional objects using ink jet printing technology.

2. Discussion of the Prior Art

Various types of image transfer techniques have been suggested in the past for imprinting images on a number of different material surfaces including cloth, wood, metal and ceramics. A very common technique, which has been widely used, is silk screening. However, such a technique is generally limited to printing on smooth, flat surfaces. Further, such technique produces a relatively low quality prints when compared to that produced by lithography, gravure, letterpress sublimation and laser printing.

When the image is to be transferred to a metal surface, prior art sublimation techniques are frequently used. For example, Blake et al, U.S. Pat. No. 3,484,342 issued Dec. 16, 1969 and Fromson et al, U.S. Pat. No. 4,201,821 issued May 6, 1980 both suggest decorating unsealed and coated anodized aluminum using sublimation techniques. However, Sublimation processes also have substantial drawbacks, particularly when the surface of the object, which is printed, is non-planar. Transferring an image or graphic to a sphere or curved, cylindrically tapered surface by means of sublimation, is extremely difficult and such an approach, if achievable at all, would typically result in a poor quality, highly distorted image.

When printing on non-planar surfaces is required, several techniques have been suggested. For example, U.S. Pat. No. 4,741,288 issued to Stirbis et al discloses an apparatus for decorating a cylindrical can. The Stirbis et al apparatus makes use of a multiple station ink supply and a transfer apparatus for transferring ink from an ink fountain to a rotatable inking blanket wheel through a plate cylinder. The apparatus includes an ink image registration adjustment apparatus and an axial and circumferential tightness control apparatus operatively associated with each plate cylinder and each ink supply and transfer apparatus. In addition to techniques involving the use of rotatable inking wheels such as described in Stirbis et al, other techniques, which have been suggested for imprinting images on non-planar surfaces, include electrophotographic imaging and magnetic imaging. As a general rule, these techniques have met with limited commercial success.

U.S. Pat. No. 5,831,641 issued to Carlson discloses a method and apparatus for imprinting images on non-planar surfaces, including the surfaces of various types of three-dimensional articles, such as baseball bats. The apparatus includes a modified ink jet plotter coupled with an article positioning apparatus which functions to automatically maintain the surface of the article to be printed within a plane substantially parallel to and slightly spaced apart from the place within which the ink jet nozzles of the ink jet plotter reside.

Another prior art technique, which is frequently used to decorate surfaces, such as anodized aluminum surfaces,

involves the use of transfer films. These films typically overlay the metal surface and undesirably, are subject to film deterioration and unattractive abrasion. A very popular prior art printing technique, which has found wide acceptance in recent years, is ink jet printing. Within perhaps the last five years this technology has become the dominant technology for printing color images and graphics in the office and home markets. Ink jet printing basically involves a process whereby ink particles are projected in a continuous stream toward the surface to be imprinted using appropriate computer control to create text and graphics on the printing substrate. A number of different types of ink jet printers/plotters are readily commercially available from sources such as Calcomp, Packard Bell, NEC Technologies and Mutoh America, Inc.

As will be better understood from the discussion which follows, the method and apparatus of the present invention overcomes most of the problems encountered in prior art attempts to print detailed images on non-planar surfaces by employing a uniquely modified prior art ink jet image transfer technique.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a method and apparatus for imprinting high quality images on non-planar surfaces, including the surfaces of various types of three-dimensional articles formed from a number of different types of materials.

Another object of the invention is to provide a method and apparatus of the aforementioned character in which the non-planar surfaces are printed using a uniquely modified ink jet image transfer technique.

Another object of the invention is to provide a method as described in the preceding paragraphs in which the image is printed on the surface of the article using a plurality of ink jet cartridges, the nozzles of which never touch the surface of the article, which is being printed.

Another object of the invention is to provide an apparatus of the character described in the immediately preceding paragraph which includes a novel article positioning apparatus which functions to controllably rotate the article to be printed and to automatically maintain the longitudinal axis of the article within a plane substantially parallel to and spaced apart from the plane within which the ink jet nozzles reside.

A specific object of the invention is to provide a method and apparatus for imprinting detailed color images on the tapered cylindrical surface such as that found on the barrel and intermediate surfaces of a baseball bat.

Another object of the invention is to provide an apparatus of the class described in which the article positioning portion of the apparatus is operably coupled with a conventional type of commercially available ink jet plotter.

Another object of the invention is to provide an apparatus for imprinting high quality images on non-planar surfaces that is simple to use, is reliable in operation and requires minimum maintenance.

By way of brief summary, a major advantage of the method and apparatus of the present invention is the ability to produce high-quality, multi-colored prints on non-planar surfaces of the character not readily adapted to pass through printing machinery, including surfaces found on a number of differently configured, three-dimensional articles such as baseball bats and the like. In this regard, a particular advantage of the apparatus of the present invention is its

ability to print high quality images on curved wood and metal surfaces without the dispensing nozzles of the ink jet cartridges of the apparatus coming into physical contact with the surface to be printed.

In one embodiment of the invention, the article holding and positioning apparatus of the invention is coupled with a conventional, mircoprocessor based digital plotter of the character having a plurality of ink jet cartridges which travel longitudinally of the print zone of the plotter. Typically, three ink jet cartridges contain ink of the three primary colors, namely red, yellow and blue. While a fourth cartridge contains black ink. This allows the computer program developed and stored in the computer memory to cause the application of a multiplicity of individual ink dots of various colors to the work surface so that, when combined by the human eye, appear as photo quality images. In operation of the apparatus of the invention, the article to be imprinted is typically rotated relative to the ink jet cartridges and the surface to be imprinted with the longitudinal axis of the article continuously maintained in a plane which is parallel to and spaced apart from the plane within which the ink jet nozzles reside.

In one form of the method of the invention a computer is used to communicate to the printing apparatus information containing the predetermined pattern to be printed which has either been previously scanned or originally generated using specialized software. The pattern information is typically stored in the computer memory and then sent via cable to the printing apparatus which preferably comprises a conventional printer having four color ink jet print heads capable of dispensing pigmented inks or dyes comprised of either a solvent or water base material. A printed circuit board operably associated with the cable controllably fires the nozzles of the print heads to spray microdots of ink onto the surface to be printed in the predetermined pattern.

According to one embodiment of the invention, the microdots have a diameter of approximately 0.0500-mm (0.002 inches) thereby enabling intricate images to be imprinted on the surface. Upon contact with the surface, the ink solidifies and leaves a digitally generated or scanned image or graphic on the surface without the ink jet nozzles ever coming into physical contact with the surface.

Images to be applied to irregular, non-linear surfaces as occur with changing diameters that are rotating at a constant angular rate can be printed to result in linear appearance by computer programming. The subject apparatus can also achieve the linear appearance by producing graphics that compensate dimensionally for the changing diameters and then, by scanning the graphic artwork, computer data can be recorded and stored for use on the subject equipment when desired.

Computer stored images can be edited on the computer monitor screen to eliminate images, add images or erase spaces for insertion of images. Such images can be nomenclature; video camera generated photo quality images (people, objects, animals, etc.). Changes can be accomplished expeditiously just prior to printing.

Using the techniques described in the preceding paragraphs, high quality images can quickly and easily be imprinted on a variety of different types of materials and upon the non-planar surfaces of a number of types of irregularly configured three-dimensional articles.

BRIEF DESCRIPTION OF THE INVENTION

FIG. **1** is a generally perspective view of one form of a modified, commercially available plotter that forms a part of the apparatus of the invention for imprinting a predetermined pattern on a surface of a three-dimensional article such as a baseball bats.

FIG. **2** is an enlarged, generally perspective view of the right hand portion of the modified commercially available plotter shown FIG. **1**.

FIGS. **3** and **3A** in combination comprise a front view of the apparatus of the invention shown in FIG. **1** following the connection to the apparatus of the novel three-dimensional article positioning subassembly the apparatus.

FIG. **4** is a generally perspective view of the right hand portion of the apparatus shown in FIG. **3A**.

FIG. **5** is a generally perspective, fragmentary view of the left hand portion of the apparatus shown in FIG. **3** showing the manner in which the handle portion of the baseball bat is mounted within the article positioning subassembly.

FIGS. **6** and **6A** when considered together comprise a view taken along line **6—6** of FIGS. **3** and **3A**.

FIG. **7** is a cross-sectional view taken along lines **7—7** of FIG. **3**.

FIG. **8** is a cross-sectional view taken along lines **8—8** of FIG. **3**.

FIG. **9** is an enlarged cross-sectional view taken along lines **9—9** FIG. **3**.

FIG. **10** is an enlarged cross-sectional view taken along lines **10—10** of FIG. **3**.

FIG. **11** is an enlarged cross-sectional view taken along lines **11—11** of FIG. **3A**.

FIG. **12** is a cross-sectional view taken along lines **12—12** of FIG. **11**.

FIG. **13** is a generally diagrammatic view of an undistorted image or pattern that will be appropriately distorted for imprinting on an article such as a baseball bat in accordance with the method of the invention.

FIG. **14** is a generally diagrammatic view of the image shown in FIG. **13** that has been suitably distorted to enable it to be imprinted on a portion of the surface of a particular size of baseball bat.

DESCRIPTION OF THE INVENTION

Referring to the drawings and particularly to FIGS. **3** and **3A**, one form of the apparatus of the invention for imprinting a predetermined image or pattern on a three-dimensional article is there illustrated and generally designated by the numeral **14**. The apparatus of this form of the invention is made up of two main components, one being a modified, commercially available type of microprocessor based, ink jet printer (FIGS. **1** and **2**) and the other comprising positioning means for holding, positioning, and rotating the article to be imprinted within the printer at a location proximate the color ink jet print heads **18** of the modified printer **16** (FIG. **3**). The primary modification made to the commercial printer involves the removal of the drive roller assemblies and their related drive mechanisms from the lower portion of the printer housing. Once this is accomplished the lower portion of the printer housing is open and has the configuration illustrated in FIG. **1** of the drawings.

While various commercially available ink jet printers and plotters can be used in combination with the positioning means of the invention, large-format and desktop printers manufactured and sold by The Hewlett-Packard Company as Designjet, Models 1050C/1055CM, 1120C and 1220C have proven satisfactory. The Designjet printer is a microprocessor-based digital printer that receives plotting

instructions from an associated host computer **20** (FIG. **1**). It is also to be understood that either a printer or a plotter apparatus could be specifically designed for a given application and could be used with positioning means of the character prently to be described in performing the method of the invention. Such an apparatus would preferably incorporate a reciprocally movable cartridge assembly that could imprint images on a stationary object.

As best seen in FIG. **1**, modified printer **16** comprises a console-type housing **22** having a base **24**, a covering **26** superimposed over base **24** and a control panel **28** which houses the control circuitry of the printer. Computer **20** functions to communicate to the control circuitry of the printer the predetermined image or graphic that is to be imprinted on the three-dimensional article. The image or graphic can be scanned or can be originally generated in the computer environment with specialized software. Typically, the computer image or graphic is stored on a hard drive and sent via a cable **28** to the control circuitry of the printer **16**. Techniques for scanning or originally generating the image or indicia or be imprinted on the three-dimensional article are well known to those skilled in the art.

Data transfer is controlled by the computer **20**, which generates and transmits to the control circuitry of the printer the necessary timing signals to properly sequence the processing of data and instructions to the printer. The printer memory typically contains the operating system to control printer operation using the control panel. The ink jet print heads **18**, which upon command, travel longitudinally of the print zone of the printer along the print head carriage **19**, are preferably of very high resolution, such as the Designjet ink jet printers sold by Hewlett-Packard. Examples of the design and operation of other prior art print heads, reservoirs and printers are described in U.S. Pat. Nos. 4,593,292; 4,459,601; 4,523,200; 4,580,147; and 4,646,106. Because of the pertinency of the aforementioned patents, each of the patents is hereby incorporated by reference as though fully set forth herein.

The ink, which is dispensed by the ink jet print heads, can be either solvent or waterbased and is carried by the cartridges in a manner generally disclosed in U.S. Pat. Nos. 4,646,106 and 4,593,292. The carriage of the printers typically contains a printed circuit board, which controls the firing of the nozzles in the ink jet print heads. In the apparatus of the present invention, the motor is also controlled from the main printed circuit assembly by the microprocessor **18** via the control circuitry housed within control panel **26**. Details concerning the construction and theory of operation of the Designjet Models 1050C/1055CM, 1120C and 1220C printers and details of the control circuitry thereof are readily obtainable from The Hewlett-Packard Company of San Diego, Calif.

Considering now the important article positioning means of the invention that is mounted within the modified printer housing **22**, this means here comprises an article positioning assembly, generally designated by the numeral **30**, that is mounted within the lower portion of the modified printer housing using appropriate connecting hardware **31** (FIGS. **6** and **6A**). In the form of the invention illustrated in the drawings, the article positioning assembly has a first end portion **32** and a longitudinally spaced, second, or left end portion **34** (FIGS. **3** and **3A**). As shown in FIG. **3A**, first end portion **32** includes first gripping means for gripping the first end of the three-dimensional article to be imprinted and rotating means for controllably rotating the three-dimensional article relative to the ink jet cartridges **18**. The second end portion **34**, as shown in FIG. **3**, includes second gripping means for gripping the second end of the three-dimensional article to be imprinted and length adjustment means for adjusting the distance between first and second gripping means. Second end portion **34** also includes height adjustment means for adjusting the height of the second gripping means.

The positioning means of the present form of the invention further comprises a guide member **36** that extends longitudinally of the modified printer housing and also comprises a carriage **40** that is slidably movable along guide member **36**. A support arm **42***a* of a support arm assembly **42** is connected to carriage **40** by an angle bracket **42***b* (FIG. **5**) and the second gripping means of the apparatus is connected to the support arm in the manner as seen in FIGS. **3**, **5** and **6**.

As previously mentioned, minimum modification of the commercially available Designjet printer is required to enable it to accept the article positioning means of the invention. Basically, all that is required is to remove the media drive mechanisms, which manipulate the media, such as planar sheets of material which are to be imprinted and to add connectors to the spaced apart printer end walls **22***a* and **22***b* to permit connection of the article positioning means thereto (FIG. **1**).

As shown in FIGS. **3A** and **4** the first gripping means of the apparatus includes a first generally cup shaped member **44** having a peripheral surface **44***a*. The rotating means of the apparatus for rotating the article to be imprinted here comprises an idler wheel **46** that is disposed in engagement with peripheral surface **44***a* of cup shaped member **44** for imparting rotation thereto upon rotation of a drive wheel **48**. As best seen in FIGS. **11** and **12**, the toothed portion **50** of the drive wheel **48** is connected to a rack **52** housing teeth **52***a*. Rack **52** is mounted on a shaft **52**, which is rotated by motor means here provided as a conventional electric motor **54**.

An important feature of the apparatus of the invention resides in fact that idler wheel **46** is adjustable relative to both wheel **48** and cup **44** so that cups of various sizes can be substituted for cup **44** in order to accept bats having either larger or smaller barrels. More particularly, as best seen in FIG. **11**, idler wheel **46** is mounted for rotation on an idler wheel support carriage **54** that is reciprocally movable from a first position shown in FIG. **11** to a second retracted position wherein carriage **54** moves to the right has viewed in FIG. **11**. Biasing means, shown here as a coil spring **56**, functions to urge carriage **54** into engagement with cup **44** and wheel **48**, that is to the left as viewed in **11**. It is apparent that by pulling on gripping portion **54***a* (FIG. **4**), idler wheel **46** can be moved to the right as viewed in FIG. **11**. This permits cup **44** to be removed from the bearing **56** that supports it (FIG. **12**) so that it can be replaced by an alternate, larger for smaller cup. However, regardless of the size of the holding cup, idler wheel **46** will be continuously urged into pressural engagement with drive wheel **48** and with the cup that is holding the bat that is to the imprinted. As shown in FIG. **12**, stub shaft **58** is affixed to an extends from cup **44** for insertion into bearing **56**. Bearing **56** is located so that the article to be imprinted, in this case a baseball bat B, is rotated about the longitudinal axis **59** of the bat, that resides within a first plane, that is parallel with a second, spaced-apart plane within which the ink jet cartridges travel.

As illustrated in figured **3** and **3A**, baseball bat "B" includes a handle portion "H", a cylindrically shaped barrel portion "C", and a tapered intermediate portion "T" which

is located between handle portion "H" and cylindrically shaped barrel portion "C". When this type of three-dimensional article is to be imprinted, a generally cup shaped member **60**, which comprises a part of the second gripping means is adapted to support handle portion "H" of the three-dimensional article in the manner shown in FIG. **3**. Similarly, the previously identified generally cup shaped member **44** of the first gripping means is adapted to support the end of the barrel shaped portion "C" of the baseball bat. As previously described, when the barrel shaped portion "C" of the baseball bat to be imprinted is either larger or smaller in diameter from that shown in the drawings, cup shaped member **44** can be removed and a larger or smaller cup shaped member can be substituted therefor. Accordingly, bats having barrel portion of various diameters can readily be accommodated by replacing cup shaped member **44** with an alternate, appropriately sized cup shaped member. As is readily apparent from a study of FIGS. **11** and **12**, by changing the size of the cup shaped member that holds the first end, or barrel of the bat, the speed of rotation of the bat about its longitudinal axis is automatically adjusted. More particularly, where the motor **54** rotates shaft **52***a* at a constant speed, the larger the cup that supports the barrel of the bat, the slower will be the speed of rotations of the bat about axis **59**. The effect of this change of rotational speed will later be discussed.

Considering now in greater detail the second gripping means of the invention this means here comprises a generally cup shaped member **60** that includes an article gripping portion **60***a* and an outwardly extending shaft portion **60***b* (FIG. **9**). Shaft portion **60***b* is mounted for rotation within a bearing **62** that is carried by a holding block **64**. Holding block **64** is, in turn, slidably received within the generally yoke shaped portion **43** of upstanding arm **42***a* of support arm assembly **42** (FIG. **8**). Holding block **64**, which forms the part of the height adjustment means of the invention for raising or lowering the height of cup **60** relative to the plane of travel of the ink jet cartridges, is held securely in position within yoke portion **43** by a threaded set screw **68** having a finger gripping head portion **68***a* at a selected height so as to maintain the longitudinal axis of the bat parallel with the path of travel of the ink jet cartridges. In this regard, it is also possible to adjust the height of cup **44** of the first gripping means, if so required, by raising or lowering a support plate **65** by a second height adjustment means. This second height adjustment means here comprises, in addition to support plate **65** an adjusting screw **67** that acts on plate **65** in the manner depicted in FIGS. **11** and **12**.

In using the apparatus of the invention to accomplish one form of the method of the invention, shaft **58** of an appropriately sized cup assembly **44** is first mounted within bearing **56**. This done, the longitudinal position of the second gripping means of the invention is adjusted using the length adjustment means of the invention to position cup **60** of the second gripping means at the correct spaced-apart location to accept the bat to be imprinted. In this regard, is to be noted that the length adjustment means includes biasing means, shown here in the form of a coil spring **70** (FIG. **6**). Spring circumscribes an elongated rod **72**, one end of which is connected to carriage **40**, and in this way functions to urge the second gripping means, including cup **60**, toward the first gripping means, or to the right as viewed in FIG. **6**. As shown in FIG. **6**, rod **72** is mounted within an adjustment block **74** that can be selectively positioned along guide **36** by loosening a setscrew **76** to roughly position cup **60** at a location approximately the length of the bat "B".

In using the apparatus of the invention, the length of the bat to be imprinted, as well as the diameter of the barrel portion C of the bat is first determined. This done an appropriately sized holding cup, such as cup **44**, is inserted into bearing **56** in the manner shown in FIG. **12**. In order to insert the holding cup **44** into bearing **56**, idler wheel **46** must be urged to the right as viewed in FIG. **11** against the urging of spring **56**. When the cup is correctly positioned within bearing **56** and the pressure exerted against idler wheel **46** is relaxed, spring **56** will urge the idler wheel into driving engagement with the peripheral surface **44***a* of the holding cup. As previously mentioned, the larger the holding cup the slower will be the rotation of the bat. Conversely, the smaller the holding cup the faster will be the rotation of the bat.

After the correct cup assembly **44** is in place, carriage **40** of the positioning means is moved along guide **36** to a location wherein the extremity of the handle of the bat can be inserted into holding cup **60** (FIG. **3**). At this same time, if so required, block **64** can be moved upwardly or downwardly by loosening set screw **68** in order to insure that the longitudinal axis of the bat is precisely parallel to the longitudinal path of travel of the ink jet heads. It is to be noted that with the bat secured within the positioning means in the manner shown in FIG. **3** and **3**A, the biasing means or spring **70** of the length adjustment means will continuously urge cup **60** into pressural engagement with the extremity of the handle portion of the bat so that cups **44** and **60** are in secure frictional engagement with the ends of the bat.

Following the correct positioning of the bat "B" within the positioning means, energization of motor **54** will cause rotation of shaft **52***a* and screw **52** which will, in turn, cause rotation of drive wheel **48** at a constant speed of rotation. As previously described herein, rotation of drive wheel **48** will, cause rotation of idler wheel **46** and the concomitant rotation of holding cup **44**. Rotation of holding cup **44**, which is in frictional engagement with the bat, will cause the bat to rotate about axis **59** at uniform rate that is governed by the diameter of the barrel portion of the bat. In this regard, when the image to be printed is, by way of nonlimiting example, a depiction of a human figure, such as a baseball player of the character shown in FIG. **13**, the image is either scanned or originally computer generated using specialized software of a character well known to those skilled in the art. Because of the tapered configuration of the bat, it is obvious that the image as shown in FIG. **13**, which is bounded by a rectangle "R" could not be imprinted on the bat because the image does not conform to the surface to be imprinted. This is due to the fact that, if the surface of the bat that is to be printed is projected into a planar configuration, the configuration would obviously be non-rectangular in shape. Therefore it is necessary to produce a distorted image that is of the character generally depicted in FIG. **14**. As indicated in FIG. **14**, the distorted image, which now generally conforms to the planar projection of the surface to be imprinted, is bounded by a trapazoid with the lower portion of the image being substantially narrowed so as to conform to the tapering of the bat. When this distorted image is printed by the printer in accordance with appropriate instructions given by to the control circuitry of the printer by host computer **20**, the image will be neatly wrapped around the barrel as well as the tapered and handle portions of the bat to produce a desired nonoverlapping result. Image distortion of the general character shown in FIG. **14** can be easily accomplished by those skilled in the art using several types of readily commercially available morphing type software, to create a file that is readable by the control circuitry of the modified microprocessor based printer being used. Experience has shown that by way of non-limiting example, photo editing software

such as that sold under the name and style "COREL" and "ADOBE PHOTO SHOP" can be used to appropriately distort the image to be imprinted.

The nature and extent of the distortion of the image to be imprinted is, of course, dependent on the configuration of the article to be imprinted. When the article has the configuration of a baseball bat, the bat must first be dimensionally analyzed to determine the character of the surface of the bat that is to be imprinted. Such an analysis can readily be accomplished by those skilled in the art and typically involves a determination of the diameter of the barrel portion of the bat and the degree of reduction in diameter or extent of taper of the tapered and handle portion upon which the image is to appear. Such a dimensional analysis of a baseball bat is relatively simple and need not be particularly precise so long as the surface to be imprinted can be projected into a planar configuration of the general character that is depicted in FIG. **14**. Once the distorted image is created and appropriately loaded into the printer and the bat is rotated in the manner previously described, the ink cartridges will move through the print zone in a conventional manner and will appropriately deposit ink onto the surface of the bat to create the desired appropriately distorted image. More particularly, as the bat rotates, the control circuitry of the printer responding to the instructions received from the preprogrammed host computer **20** will direct the ink jet heads to controllably deposit ink onto the surface of the bat in accordance with the predetermined software that has been developed to produce the desired image on the baseball bat.

Having now described the invention in detail in accordance with the requirements of the patent statutes, those skilled in this art will have no difficulty in making changes and modifications in the individual parts or their relative assembly in order to meet specific requirements or conditions. Such changes and modifications may be made without departing from the scope and spirit of the invention, as set forth in the following claims.

I claim:

1. In combination with a modified microprocessor-based printer that produces copies of computer data based on printing instructions received from a host computer, said printer being of a character having a carriage which carries at least one ink jet cartridge for movement along the length of a print zone of the printer within a first plane and means for controlling firing of a nozzle of the ink jet cartridge, the improvement comprising positioning means for holding within the printer a three-dimensional article having a first end, a second end, a longitudinal axis and a curved surface upon which the computer data is to be imprinted, said positioning means functioning to controllably position the three-dimensional article within the printer in a manner such that the longitudinal axis of the article is at all times during the printing operation maintained within a second plane that is parallel to and spaced-apart from the first plane, said positioning means comprising an article positioning assembly mounted within the modified microprocessor based printer, said article positioning assembly comprising:

(a) a first end portion including:

(i) first gripping means for gripping the first end of the three-dimensional article, said gripping means comprising a first holding cup removably connected to said first end portion, said first holding cup having a peripheral portion and an article gripping portion; and

(ii) rotating means for controllably rotating the three-dimensional article relative to the ink jet cartridge, said rotating means comprising an idler wheel rotatably carried by said first end portion for engagement with said peripheral portion of said first holding cup and a drive wheel rotatably carried by said first end portion for rotating said idler wheel; and

(b) a second end portion, including second gripping means for gripping the second end of the three-dimensional article, said second gripping means comprising a second holding cup and adjustment means for adjusting the distance between said first and second gripping means.

2. The combination as defined in claim **1** in which said positioning means further includes a guide member connected to the modified printer and in which said second end portion includes a carriage slidably movable along said guide member and a support arm connected to said carriage, said second gripping means being connected to said support arm.

3. The combination as defined in claim **1** in which said article positioning assembly further comprises height adjustment means for adjusting the position of said second gripping means relative to the first plane.

4. The combination as defined in claim **1** in which said article positioning assembly further comprises second height adjustment means for adjusting the position of said first gripping means relative to the first plane.

5. The combination as defined in claim **1** in which said article rotating means further comprises:

(a) an idler wheel support carriage that is movable between a first position proximate said first holding cup and a second retracted position spaced from said first holding cup, said idler wheel being rotatably mounted on said idler wheel support carriage; and

(b) biasing means for yieldable urging said idler wheel support carriage toward said first position.

6. A method for imprinting an image on a portion of the surface of a baseball bat by using a modified microprocessor-based printer that includes control circuitry that functions to cause the printer to produce a copy of computer data based on printing instructions received from a host computer, the printer being of a character having a carriage which carries at least one ink jet cartridge having a nozzle for movement along the length of a print zone of the printer within a first plane and means for controlling the firing of a nozzle of the ink jet cartridge, the modified microprocessor based printer comprising an article positioning assembly for holding the bat within the printer in a manner such that the longitudinal axis of the baseball bat is at all times during the printing operation maintained within a second plane that is parallel to and spaced apart from the first plane, said method comprising the steps of;

a. analyzing the baseball bat to determine the configuration of the portion of the surface of the baseball bat that is to be imprinted;

b. positioning the baseball bat within the article positioning assembly;

c. rotating the baseball bat about its longitudinal axis of the base;

d. producing a non-distorted image;

e. distorting said non-distorted image in a manner to produce a distorted image that corresponds with the surface of the baseball bat that is to be imprinted;

f. using the host computer, transmitting the printer instructions to the printer instructing the printer to fire the nozzle of the ink jet cartridge in a manner to print said distorted image on the rotating baseball bat.

7. The method as defined in claim **6** in which the modified printer carries a plurality of ink jet cartridges each having a nozzle and in which the printer is instructed by the host computer to fire the nozzles of the plurality of ink jet cartridges to produce the distorted image on the rotating baseball bat.

8. The method as defined in claim **6** in which the non-distorted image is bounded by a generally rectangular shape and in which the distorted image is bounded by a generally trapezoidal shape.

9. The method as defined in claim **8** in which the image depicts a human figure.

10. In combination with a modified microprocessor-based printer that produces copies of computer data based on printing instructions received from a host computer, said printer being of a character having a carriage which carries at least one ink jet cartridge for movement along the length of a print zone of the printer within a first plane and means for controlling firing of a nozzle of the ink jet cartridge, the improvement comprising positioning means for holding within the printer a three-dimensional article having a first end, a second end, a longitudinal axis and a curved surface upon which the computer data is to be imprinted, said positioning means functioning to controllably position the three dimensional article within the printer in a manner such that the longitudinal axis of the article is at all times during the printing operation maintained within a second plane that is parallel to and spaced-apart from the first plane, said positioning means comprising an article positioning assembly mounted within the modified microprocessor based printer, said article position assembly comprising:

i. a first end portion including first gripping means for gripping the first end of the three-dimensional article and rotating means for controllably rotating the three-dimensional article relative to the ink jet cartridge;

ii. a second end portion including second gripping means for gripping the second end of three-dimensional article and adjustment means for adjusting the distance between said first and second gripping means;

said positioning means further includes a guide member connected to the modified printer and in which said second end portion includes a carriage slidably movable along said guide member and a support arm connected to said carriage, said second gripping means being connected to said support arm; and

said rotating means comprises a drive wheel in engagement with said generally cup shaped member for imparting rotation thereto at a first rate.

11. The combination as defined in claim **10** in which said article positioning assembly further comprises height adjustment means for adjusting the position of said second gripping means relative to the first plane.

12. The combination as defined in claim **10** in which said article positioning assembly further comprises height adjustment means for adjusting the position of said first gripping means relative to the first plane.

13. The combination as defined in claim **10** in which said first gripping means comprises a holding cup having a peripheral portion and an article gripping surface for gripping the first end of the three dimensional article and in which said article rotating means comprises:

d. an idler wheel rotatably carried by said first end portion of the article positioning assembly, said idler wheel being in engagement with said peripheral portion of said holding cup;

e. a drive wheel rotatably carried by to said first end portion of the article positioning assembly, said drive wheel being in driving engagement with said idler wheel; and

f. motor means for rotating said drive wheel.

14. The combination as defined in claim **13** in which said article rotating means further includes an idler wheel support carriage that is movable between a first position proximate said first holding cup and a second, retracted position spaced from said first holding cup, said idler wheel being rotatably mounted on said idler wheel support carriage.

15. The combination as defined in claim **14** in which said holding cup is removably connected to said first end portion.

16. The combination as defined in claim **14** further including biasing means carried by the first end portion and operably associated with said idler support carriage for yieldably urging said idler support carriage toward said first position.
